

Computer Architecture & Concurrency – COMP0008

Lecture 2 Part 1: Abstracting the machine

Kevin Bryson

K.Bryson@ucl.ac.uk

Darwin Building Room 632.

Overview of the Lecture

- Lecture 1 was very much an overview of lots of ideas about computer architecture and concurrency concepts.
- In this lecture I am going to draw together a few key ideas from this previous lecture to begin looking at the architecture of a MIPS32 machine.
- This part will look at how a computer can be abstracted in terms of a von Neumann architecture and how this relates to real hardware.

EDVAC and von Neumann Architecture

First Draft of a Report
on the EDVAC

by
John von Neumann

Contract No. W-670-ORD-4926

Between the
United States Army Ordnance Department
and the
University of Pennsylvania

2.0 MAIN SUBDIVISIONS OF THE SYSTEM

2.1	Need for subdivisions	1
2.2	First: Central arithmetic part: CA	1
2.3	Second: Central control part: CC	2
2.4	Third: Various forms of memory required: (a)-(h)	2
2.5	Third: (Cont.) Memory: M	3
2.6	CC, CA (together: C), M are together the associative part. Afferent and efferent parts: Input and output, mediating the contact with the outside. Outside recording medium: R	3
2.7	Fourth: Input: I	3
2.8	Fifth: Output: O	3
2.9	Comparison of M and R, considering (a)-(h) in 2.4	3

An abstract analogy for a real computer ...

- The *Little Man Computer* (LMC) was originally created by Dr. Stuart Madnick at MIT in 1965 as a simple analogy for a real computer. It is a good analogy since it is still largely valid 50 years later.
- CPU (Central Processing Unit)
- RAM (Random Access Memory ... Main Memory)
- Buses & Input/Output
- Assembly Language
- Machine Code

The LMC computer follows this “stored program” von Neumann Architecture ...

But is this really like a modern computer?

Real hardware ... my first Dell PC ... (“Dell Boy” now lives in my attic)

A typical Motherboard

Case
Back

Case
Front

Where does the CPU go ?

Where does the primary memory fit ?

Where does the hard disks fit ?

Where is the bus?

Original IBM PC External Bus just consists of lots of wires that carry binary signals ...

0 volts = “0” = off and +5 volts = “1” = on

- 20 bit “**address lines**” can address $2^{20} = 1\text{MB}$ of locations.
- 8 bit “**data lines**” can send a byte of data at a time.
- Control lines include read/write, clock and ground.

Interaction between CPU and Memory

More detailed view of a PC ... lots of different types of buses
